New genus of Cricetodontinae (Rodentia: Cricetidae) from the Late Miocene of Kazakhstan

Vladimir S. Zazhigin

ABSTRACT. The new genus *Rhinocerodon* gen. n., and three new species *R. pauli* sp. n., *R. seletyensis* sp. n., and *R. irtyshensis* sp. n. are described from the Late Miocene of Kazakhstan. These forms represent a new group of peculiar lophodont hamsters, *Rhinocerodontini* trib. n.

KEY-WORDS: *Rhinocerodon* gen. n., Cricetodontinae, Late Miocene, Kazakhstan.

New genus of Cricetodontinae (Rodentia: Cricetidae) from the Late Miocene of Kazakhstan

Vladimir Zazhigin [zazhigin@ginras.ru], Geological Institute of the Russian Academy of Sciences, Pyzhevskiy per., 7, Moscow 119017, Russia.

**Новый род Cricetodontinae (Rodentia: Cricetidae) из позднего миоцена Казахстана**

**В.С. Зажигин**

**Резюме.** *Rhinocerodon* gen. n. описан из позднего миоцена Казахстана. Новый род представлен тремя видами (*R. pauli* sp. n., *R. seletyensis* sp. n., и *R. irtyshensis* sp. n.) из трех разновозрастных местонахождений (MN12, MN13, MN13/14). *R. pauli* sp. n. и *R. irtyshensis* sp. n. принадлежат одной филетической линии. В составе подсемейства Cricetodontinae выделена особая триба лофонтных хомяков, *Rhinocerodontini* trib. n.

**Ключевые слова:** *Rhinocerodon* gen. n., Cricetodontinae, поздний миоцен, Казахстан.

**Introduction**

The history of hamsters of the subfamily Cricetodontinae is well studied based on the fossil assemblages of Europe and Asia Minor (Mein & Freudenthal, 1971; Bruijn et al., 1993, Bruijn & Ünay, 1996, and others). The fossil record of this group to the east of the Ural is much less detailed. Two species of the genus *Tsaganoeoticus* Topachevsky et Skorik, 1988 [=Goviceretodon Qiu, 1996] were described both from the Miocene of Kazakhstan (Topachevsky & Skorik, 1988; Bendukidze, 1993) and from China (Qiu, 1996).

Remains of the new genus of Cricetodontinae were found in several Neogene localities of Kazakhstan in the south of the West Siberian Plain. In the locality Gusiniyi Perelet in the suburbs of the city of Pavlodar the remains of the new genus come from two beds of different age. The older one is confined to the fossiliferous lens in the deposits of the Pavlodar Formation. This site, Pavlodar 1A (MN12), yielded the majority of mammal remains of the Pavlodar Complex. The material of the new genus is known from this locality since 1963 based on the collection of the present author and one of P.F. Savinov (Almaty). Because the Savinov’s collection was more representative, we decided that description of the taxon should be presented by P.F. Savinov. Unfortunately, before his death Pavel Savinov could only mention the genus as *Rhinocerodon* gen. n. (Savinov, 1988: 29), a nomen nudum. In the subsequent list of mammals of the Pavlodar Complex this form was cited by me as Ruscinomyinae gen. n. (Zazhigin & Zhykin, 1984: 31) to prevent a coining of a new generic name before Savinov. Recently L.A. Tyutkova (2003: 219) in her list of the Pavlodar mammal fauna gave a new name, *Rhinoceromys* (=*Rhinocerodon* Savinov, 1988) savinovi gen. et sp. n. This publication does not mention a holotype and place where the collection is housed. Therefore, according to the ICZN Article 16.4 the latter name is unavailable. The present publication validates the name proposed by Savinov.

The second fossiliferous bed (the locality Pavlodar 1B) of Gusiniyi Perelet is associated with grey cross-bedded sand of the Rytovo Formation overlying the red clay of the Pavlodar Formation. Small mammal fauna of the Pavlodar 1B belongs to the Cherlak Complex, which broadly corresponds to the Pontian localities of Ukraine. Because the position of the Miocene-Pliocene boundary in the continental deposits is so far ambiguous, the fauna of the Cherlak Complex is dated here in the range of the terminal Miocene or the basal Pliocene (MN13/MN14).

The third locality with remains of the new genus is Selety 1A situated at the Selety River, 4 km upstream the Ilyinka village. Fossil remains originate from the deposits of the Late Miocene Kedey Formation. The association of small mammals (*Lophocricetus vinogradovi* Savinov, 1970 and *Paranourosorex seletyensis* Storch et Zazhigin, 1996) allows to date this site as the lower part of MN13.
Each of the above mentioned localities yielded a separate species of the new genus. Materials are housed in the collection of the Geological Institute of the Russian Academy of Sciences (abbreviated GIN), Moscow.

**Systematic Paleontology**

Order Rodentia Bowdich, 1821

Family Cricetidae Fischer, 1817

Subfamily Cricetodontinae Stehlin et Shaub, 1951

Genus *Rhinozeros* gen. n.

**Type species.** *Rhinozeros pauli* sp. n., Upper Miocene of Kazakhstan (MN12).

**Included species.** *R. seletyiensis* sp. n., Upper Miocene of Kazakhstan (lower MN13); *R. irtyshensis* sp. n., terminal Miocene or basal Pliocene of Kazakhstan (upper MN13 or lower MN14).

**Etymology.** From Greek *Rhinozeros* (rhino) and odus, odontos (tooth).

**Diagnosis.** Size medium. Molars brachydont. Molar crowns relatively low, lophodont. Height of lophs and lophids equals to that of cones and conids. Enamel walls of crowns nearly uniformly thick, occlusal surface flat already in early wear stages. Mesocones and mesoconids absent. Lateral margins of m1 antercone labially (by anterolophid and lingually (by metaconid) connected with protoconid and metaconid forming a sickle-shaped structure. Metaconid connected with protoconid by metaconid II. Upper part of the latter does not reach occlusal surface. In late wear stages metaconid II joins to the sickle-shaped structure and closes anterofossettid. Hypoconid small, strongly shifted anteriorly. Enamel connected with hypoconid by a broad hypolophid. Posterolophid strong, and hypoconid and entolophid form a horse-shoe structure. In old specimens this structure closed into an irregular circle drawing a posterofossettid. Proto- and anterostirid small or absent. Size of labial sinusid variable. Posterostirid does not extend crown base. Mesostirid deepest and longest. Mesostirid together with labial sinusid divide m1 occlusal surface into two parts connected by narrow and long entolophid. m2 and m3 lack lingual branches of anterolophid and have narrow and shallow posterior sinusid. M1-2 have four roots. All cones of M1 and M2 strongly compressed, paracorne and metacone notably pointed. In M1 relatively broad protocone branches connected to long and narrow anterconid and paracorne. Anterostirid divided into nearly equal parts by anterolophid that does not reach occlusal surface. Posterolophid connected with metaconid and hypoconid. Metaloph I and anterior branch of hypoconid with endoloph forming a closed field with large posterostirid inside. Endoloph connected with posterior part of paracorne and not linked with protocone. Endo-, meso-, and anterostirid of M1 broad and deep. M2 paracorne connected with anterconid and endoloph. M2 protecone relatively large, strongly compressed, occasionally linked with paracorne or endoloph. Short endoloph connects to posterior structure identical to that of M1. Dentary deep, the masseter platform wide. Masseter crests strong, diverging at a blunt angle. Mental foramen placed below m1 anterior root at level of masseter platform angular point.

**Differential diagnosis.** Differs from all genera of the Cricetodontinae in the structure of m1: the antercone is laterally connected with the protoconid and the metaconid, the hypoconid is strongly shifted anteriorly; and M1-M2: by endoloph-based formation of the closed structure comprising hypocone, posteroloph, and metacone.

*Rhinozeros pauli* sp. n.

Figs. 1; 2A, B. D. E, K.

**Etymology.** In honor of paleontologist Pavel Fedorovich Savinov.

**Holotype.** GIN 640/528, left m1.

**Referred material.** Fragmentary left dentary with m2 and m3; isolated teeth: five M1, four M2, four m1, three m2, and one m3. Collected by V.S. Zazhigin in 1963-1965, 1976, and 1980.

**Type locality.** Pavlodar I A, Giusiny Perelet, Pavlodar city, Kazakhstan.

**Stratigraphic level.** Pavlodar Formation, MN12, Upper Miocene.

**Description.** The basic molar characters coincide with the generic diagnosis given above. Individual variability is low. Of five available m1 the anterofossettid is absent in one specimen. The depth of the posterostirid in all lower molars is less than that of the mesostirid. The posterostirid of m3 is likely obliterated very early. Size of the hypocristid in m1 is variable. Labial branch of the anterolophid in m2 and m3 is short. The lingual margins of the posterolophid and entolophid in m2 and m3 are very close to each other, the protoconid is relatively small. The M1 anterocone has a weak lingual bulge that disappears with early wear. Four of five M1 have mesostylid and two M1 have endostylid. Of the four M1 one molar does not show a link of the protocone and metacone.

**Measurements.** Length x width of crowns are measured in mm at occlusal surfaces: m1: 2.30 x 1.25 (GIN 640/528, holotype); 2.30 x 1.35 (GIN 640/530); 2.30 x 1.25 (GIN 640/531); 2.30 x 1.25 (GIN 640/532); 2.35 x 1.30 (GIN 640/533); m2: 1.40 x 1.00 (GIN 640/536); 1.95 x 1.35 (GIN 640/535); 1.95 x 1.55 (GIN 640/534); 1.80 x 1.25 (GIN 640/529); m3: 1.60 x 1.20 (GIN 640/529); 1.60 x 1.30 (GIN 640/537); M1: 2.5 x — (GIN 640/538); 2.40 x 1.50 (GIN 640/539); 2.70 x 1.35 (GIN 640/540); 2.50 x 1.35 (GIN 640/541); 2.60 x 1.50 (GIN 640/542); M2: 1.65 x 1.30 (GIN 640/543); 1.75 x 1.40 (GIN 640/544); 1.70 x 1.60 (GIN 640/545); 1.65 x 1.25 (GIN 640/546); Maximal crown height: m1, 1.05 (GIN 640/528, holotype); m2, 1.50 (GIN 640/536, unworn); M1, 1.30 (GIN 640/540); M2, 1.35 (GIN 640/544).

**Remarks.** In 1982 I collected the single m3 of *Rhinozeros* sp. in deposits of the lower Macorian of Ukraine, the locality Bereznegoveatoe (see Gozhik &
New Miocene cricetodontine from Kazakhstan

Figure 1. Molars of *Rhinocerodon pauli* sp. n. in occlusal (A–H), labial (I), and lingual (J) views. Pavlodar 1A locality, Gusinya Perelet, Pavlodar city, Kazakhstan; Pavlodar Formation, MN12, Upper Miocene.

A — GIN 640/530, left m1; B — GIN 640/529, left m2; C — GIN 640/529, left m3; D — GIN 640/531, left m1; E — GIN 640/535, right m2; F — GIN 640/537, right m3; G, I and J — GIN 640/528, left m1, holotype; H — GIN 640/536, left m2, unworn.

Prisyazhnyuk, 1978). This specimen (1.5 x 1.20 mm) lacks posterosinusid, whereas the posteriolophid is not worn. In size and structure it is very similar to the m3 GIN 640/537 (Pavlodar 1A) with the very weak and small posteriolophid. It is possible that the Pavlodarian form can have m3 without posterosinusid as well.

**Distribution.** The type locality.

*Rhinocerodon seletensis* sp. n.

Fig. 2C, H, I

**Etymology.** From Selety River.

**Holotype.** GIN 951/1033, fragmentary left dentary with m1–m3.

Figure 2. Molars of *Rhinocerodon pauli* sp. n. (A, B, D, E, K; Pavlodar 1A locality, Gusinya Perelet, Pavlodar city; Pavlodar Formation, MN12, Upper Miocene). *R. seletensis* sp. n. (C, H, I; Selety 1A locality, Selety River; Kedey Formation, lower MN13, Upper Miocene) and *R. tryskhensis* sp. n. (F, G, J; Pavlodar 1B locality, Gusinya Perelet, Pavlodar city; Rytovo Formation, terminal Miocene [MN13] or basal Pliocene [MN14]) from Kazakhstan in occlusal (A–H) and lingual (I–K) views.

A and K — GIN 640/542, right M1; B — GIN 640/546, right M2; C — GIN 951/1033, left m1–3, holotype; D — GIN 640/539, left M1; E — GIN 640/544, right M2; F and J — GIN 640/3015, left m1, holotype; G — GIN 640/3016, right m3; H and I — GIN 951/1036, left M1

**Referred material.** Fragmentary right dentary with m2 and alveoli of m1 and m3; isolated teeth: two M1, fragment of m1 with preserved anteroconid, protoconid, and metaconid. Collected by V.S. Zazhigin in 1980, and by V.S. Zykin in 1983.

**Type locality.** Selety 1A, Selety River, Kazakhstan.

**Stratigraphic level.** Kedey Formation, lower MN13, Upper Miocene.

**Description.** Structure and size of m1 and M1 as in the type species. Both M1 specimens lack styles. m2 and, particularly, m3 are relatively large compared to m1. Labial branches of anteriolophid in m2 and m3 are well developed. The sinusids of m2 and m3 are well
developed and present till late wear stages. The structure of the dentary as given in the generic diagnosis.

**Measurements.** The length of the toothrow (m1-m3) in GIN 951/1033, holotype is 6.05. Length × width of molars in GIN 951/1033, holotype: m1: 2.20 × 1.35; m2: 2.10 × 1.55; m3: 1.95 × 1.60. Length and width of other molars: m2: 2.00 × 1.50 (GIN 951/1034); M1: 2.40 × 1.35 (GIN 951/1035); 2.45 × 1.25 (GIN 951/1036).

**Comparison.** The new species is distinct from *R. pauli* sp. n. in larger m2 and, particularly, m3; in more developed branches of the anterolophid and deeper sinuoid of these teeth.

**Distribution.** The type locality.

*Rhinocerodon irtyshensis* sp. n.

Fig. 2F, G, J.

**Etymology.** After Irtsh River.

Holotype, GIN 640/3015, left m1.

**Referred material.** One m3. Material collected by V.S. Zazhigin in 1976 (the holotype) and 1980.

**Type locality.** Pavlodar IB, Gusyini Perelet, Pavlodar city, Kazakhstan.

**Stratigraphic level.** Rytoo Formation, terminal Miocene (MN13) or basal Pliocene (MN14).

**Description.** Molar crowns are relatively narrow. The m1 protocionid, anterconid, and metaconid are placed very close to each other; the metalophid early joins the protoconid and forms a shallow anterofossettid. The anterconid shows a labial branch that disappears early with the wear. The entoconid broadly connects with the hypaconid and with the broad and long posteroconid. The hypoconid is shallow, fuses with the ectolophid at early wear stages. The posterolusinsid is relatively broad but shallow. The posterofossettid is formed at early wear stages but later than the anterofossettid. The mesosinuid is broad and deep. Small mesostylid and ectostylid are present. The anitosinuid is small and shallow. The m3 lacks the posterofossettid. The labial sinuid and anterodinuid are strongly reduced. The mesosinuid is broad and deep.

**Measurements.** Length and width: m1: 2.70 × 1.20 (GIN 640/3015, holotype); m3: 1.70 × 1.45 (GIN 640/3016). Maximal crown height in GIN 640/3015, holotype is 1.60; in m3 - 1.50.

**Comparison.** The new species differs from *R. pauli* sp. n. and *R. seletyensis* sp. n. in the presence of the labial branch of anterolophid, in narrow and long m1, and in early developed fossettid by reduction of the labial sinuid and anterodinuid.

**Distribution.** The type locality.

**Discussion**

The assignment of the genus *Rhinocerodon* gen. n. into Cricetodontinae is based mainly on the lower molars structure. The dental trends studied for the fossil genus *Deperetornys* Mein et Freudenthal, 1971 (Bruijn et al., 1993) are helpful in elucidation of systematic position of many Miocene Cricetodontinae. They are likely developed in many lineages in parallel. These trends are manifested in *Rhinocerodon* gen. n. to the maximal extent. They include: 1) increase of the crests connecting cusps; 2) reduction of the posterior branch of the hypoconid; 3) reduction of the ectolophid; 4) development of the parallel fusion of crests of the protoconid and metaconid with the anteroconid. The height of crests gets equal to that of cusps in lower and upper molars. The posterolophid completely fuses with hypoconid. The ectolophid is reduced, and lateral margins of the anterolophid connect with the protoconid and metaconid. Also reduced are the mesocone and mesoconid, lingual branches of the entoloph in M2 and those of the anterolophid in m2 and m3. m2 and m3 became similar to the molars of *Hispanomys* Mein et Freudenthal, 1971. M1 and M2 of *Rhinocerodon* gen. n. acquired characters that differ from other Cricetodontinae.

Molar morphology and stratigraphic position of the species of *Rhinocerodon* gen. n. points to the presence of the two phyletic lineages. The oldest and youngest forms, *R. pauli* sp. n. and *R. irtyshensis* sp. n., likely belong to the same phyletic line. This is indicated by relatively narrow m2 and m3, reduced posterolusinsid in these molars of the both species. *R. seletyensis* sp. n. represents another lineage. It is notably stratigraphically younger than *R. pauli* sp. n. but has more primitive characters, like stronger developed labial branches of anterolophid and posterolusinsid in m2 and m3. The m3 of *R. seletyensis* sp. n. is larger than in *R. pauli* sp. n.

The specific structure of the m1, M1, M2, and dentary of *Rhinocerodon* gen. n. makes it distinct from all genera of the tribes of the Cricetodontinae. In my view, the genus level characters of *Rhinocerodon* gen. n., its species diversity, and the presence of several phyletic lineages suffice the erection of the new tribe *Rhinocerodontini* trib. nov.

The history of the tribe *Rhinocerodontini* trib. n. is known for a relatively short interval spanning the Late Miocene to basal Pliocene. The known diversity of Cricetodontinae of Europe and Asia Minor gives no clues for the affinities of the *Rhinocerodon* gen. n. Likewise, no ancestral forms of the new genus are so far known in the Central Asia among the unpublished collections of *Cricetodon* Lartet, 1850, *Tsaganocricetus*, and *Hispanomys* stored in the Geological Institute RAS, Moscow. These materials reveal insufficiently the Miocene history of the Cricetodontini in Central Asia. In spite of the poorly known fossil record of the region, it is likely that the ancestry of *Rhinocerodon* gen. n. should be looked for in the faunas of the Middle Miocene of the Central Asia.

**ACKNOWLEDGEMENTS.** I thank A.S. Tesakov for the English translation and preparation of illustrations and A.V. Lopatin for discussion and helpful comments.
